Video Link: [Website Video](#)

1. Main Page:

The first page of our website includes login and signup for the people involved, such as customers, restaurants, and delivery executives. We have also added an “About Us” page to deliver specific statistics and introduce the team.

The home page for our web application looks like the one above.

```
@app.route('/')
def home():
    return render_template('home.html')
```

Coming to Login and Signup, we first talk about the Sign-up page:

The sign-up page for our system looks as shown below. The page consists of three options to either sign up as a user, restaurant or delivery agent. We could choose any of these options depending on our use case. Each button takes the user to their respective sign-up page.

```
@app.route('/signup', methods=['GET', 'POST'])
def signup():
    return render_template('signup.html')
```

Sign Up

Sign Up

Sign Up

Sign Up

Already have an account [login](#)

After choosing any one of the options, We need to fill in the corresponding details. All the mentioned fields are mandatory. Each signup page is customised as per the user's authorisation. For example, if the user wants to sign up as a Delivery Agent, the page will be shown accordingly.

Delivery Agent Signup

First Name

Middle Name

Last Name

Email

dd-mm-yyyy

Vehicle Number

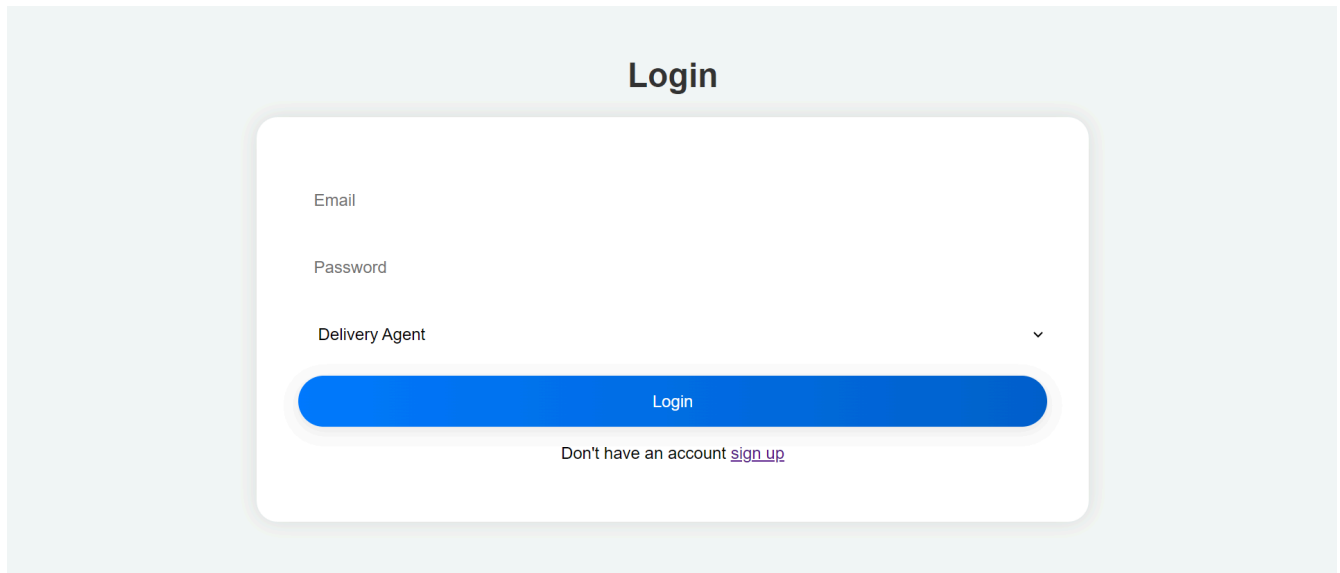

Phone Number

Password

Location

Sign Up

Now, let us talk about the Login page:

The image shows a login form titled "Login" centered on a light blue background. The form is a white rounded rectangle containing three input fields: "Email", "Password", and "Delivery Agent". The "Delivery Agent" field has a small downward arrow on its right side, indicating a pull-down menu. Below these fields is a prominent blue button with the text "Login". At the bottom of the form, there is a link that says "Don't have an account [sign up](#)".

On a single page, we keep the email, password and a pull-down menu. The concerned user will select their role, and based on that, an appropriate check is made to check if any such account with the provided password, user email and role exists or not.

If the user is a restaurant or delivery executive, they get redirected to their user details page on the condition of a successful login. If it is a customer, they get redirected to the dashboard page. In the case of a failed login, the details must be re-entered.

There are two login methods: GET and POST. Once someone logs in, details of “username”, “password”, and “authority” (customer/restaurant/delivery executive) are checked. For authority division in code, we use three boolean variables, namely customerbool, restbool and agentbool. For ex, for customers, customerbool = True, restbool == agentbool == False.

Apart from this, we also check whether the presence of *’* is for potential SQL injection attacks. The delivery executives see their user details and deliveries delivered before or in transit. The restaurants would see their basic details, the history of delivered orders and the current menu items they serve.

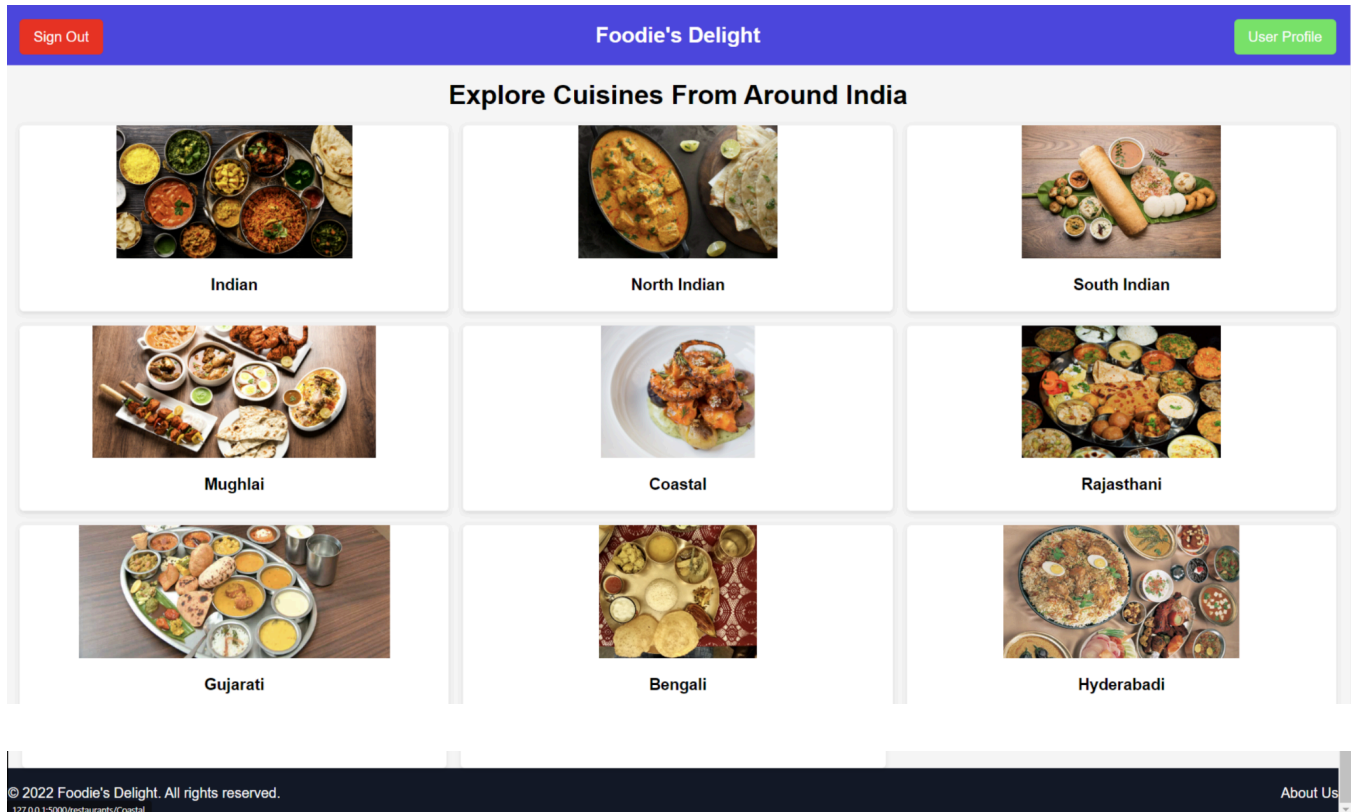

```

# login for all
@app.route('/login',methods=['GET', 'POST'])
def login():
    msg = ''
    if request.method == 'POST' and 'useremail' in request.form and 'password' in request.form and 'authority' in request.form:
        useremail = request.form['useremail']
        password = request.form['password']
        authority = request.form['authority']
        session['addr_ID'] = None
        cursor = mysql.connection.cursor(MySQLdb.cursors.DictCursor)
        if (authority == "Customer"):
            if("'" in useremail):
                msg = "Single Quote (') is not allowed in username field."
                flask.flash(msg)
                return redirect(url_for('login'))
            cursor.execute("SELECT * FROM Customers WHERE contact_details->>'$.email' = %s AND password = %s", (useremail, password,))
            account = cursor.fetchone()
            if account:
                session['customerbool'] = True
                session['restbool'], session['agentbool'] = False, False
                session['customer_id'] = str(account['customer_id'])
                cursor.execute("select address_ID from customer_address where customer_id=%s", (session['customer_id'],))
                addr_ID = cursor.fetchall()
                session['addr_ID'] = addr_ID[0]
                msg = 'Logged in successfully !'
                flask.flash(msg)
                return redirect(url_for('index'))
            else:
                time.sleep(2)
                msg = 'Incorrect username / password !'
        elif (authority == "Delivery Agent"):
            cursor.execute("SELECT * FROM delivery_agent WHERE email = %s AND password = %s", (useremail, password, ))
            account = cursor.fetchone()
            if account:
                session['agentbool'] = True
                session['customerbool'], session['restbool'] = False, False
                session['agent_ID'] = account['agent_id']
                msg = 'Logged in successfully !'
                flask.flash(msg)
                return redirect(url_for('index_deliveryagent'))
            else:
                time.sleep(2)
                msg = 'Incorrect username / password !'
        elif (authority == "Restaurant"):
            cursor.execute("SELECT * FROM Restaurant WHERE contact_details->>'$.email' = %s AND password = %s", (useremail, password, ))
            # cursor.execute(f"SELECT * FROM restaurant WHERE email='{useremail}' AND password='{password}'")
            account = cursor.fetchone()
            if account:
                session['restbool'] = True
                session['agentbool'], session['customerbool'] = False, False
                session['restaurant_ID'] = account['restaurant_id']
                msg = 'Logged in successfully !'
                flask.flash(msg)
                return redirect(url_for('restaurant_details'))
            else:
                time.sleep(2)
                msg = 'Incorrect username / password !'
        else:
            time.sleep(2)
            msg = 'Incorrect username / password !'
            flask.flash(msg)
    return render_template('login.html', msg = msg)

```

2. Customer Pages:

Dashboard for customers:

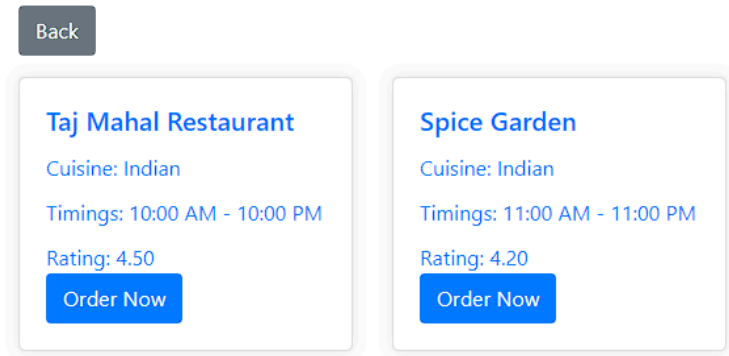

```
<h2 class="text-3xl font-bold text-center my-4">
  Explore Cuisines From Around India
</h2>
<ul class="grid grid-cols-1 md:grid-cols-3 gap-4 px-4">
  {% for cuisine in cuisines %}
  <li class="cuisine-card hover:bg-gray-100">
    <a
      href="{{ url_for('restaurants_by_cuisine', cuisine_type=cuisine.cuisine_type) }}"
      class="flex flex-col items-center justify-center"
    >
      
      <p class="cuisine-name text-lg">{{ cuisine.cuisine_type }}</p>
    </a>
  {% endfor %}
```

Each cuisine is fetched and has an image for an appealing visual appearance.

The user can select the cuisine of their choice, and restaurants are displayed inside them. Upon selecting a particular cuisine, let us say “Indian”, the following page shows up:

For the restaurants, details like Name, Cuisine type, operating times and rating are displayed. The “Back” button helps us to navigate back to the cuisine dashboard. We get redirected to the `restaurants/{cuisine_type}` page:

Restaurants

```
@app.route('/restaurants/<cuisine_type>')
def restaurants_by_cuisine(cuisine_type):
    cur = mysql.connection.cursor()

    # Execute query to fetch restaurants by cuisine type
    cur.execute('SELECT * FROM restaurant WHERE cuisine_type = %s', (cuisine_type,))
    restaurant_data = cur.fetchall()
    restaurant_columns = [col[0] for col in cur.description]
    restaurants = [dict(zip(restaurant_columns, row)) for row in restaurant_data]

    return render_template("/customers/restaurants.html", cuisine_type=cuisine_type, restaurants=restaurants)
```

[WHERE clause]

After the available restaurants are shown for a cuisine, click on “Order Now”. After clicking on “Taj Mahal Restaurant”, we get the below page. Items served by the restaurant are visible with information like Price, Rating, Type of food, Orders (number of times the food item has been ordered before), Availability (0 - not available, 1 - available right now), Item quantity (0 initially as not selected for order, here you can increase the quantity) and Notes for any special instructions to be given to the restaurant for a particular food item.

Finalize Order

For each restaurant, to display the items it serves, we use a for loop and fetch each food item and display its Price, Rating, Type, Orders, Availability and Vegetarian (1 if yes, 0 if not).

```
{% for item in restaurant_name %}
<h1 class="text-center mb-4">{{ item.restaurant_name }}</h1>
{% endfor %}
<div class="row">
  {% for food in food_items %}
    <div class="col-md-6 col-lg-4">
      <div class="menu-item">
        <h5>{{ food.item_name }}</h5>
        <p>Price: {{ food.item_price }}</p>
        <p>Rating: {{ food.item_rating }}</p>
        <p>Type: {{ food.item_type }}</p>
        <p>Orders: {{ food.order_count }}</p>
        <p>Availability: {{ food.availability }}</p>
        <p>Vegetarian: {{ food.vegetarian }}</p>
        <p>
          Item Quantity: <span id="order-count-{{ food.item_id }}">0</span>
        </p>
      </div>
    </div>
  {% endfor %}
</div>
```

There is a “Finalize Order” button, which takes you to payment after you have selected your order. On clicking the button, a dialogue box will appear stating which payment method you would like to use. We have three options, namely cash, UPI, and card.

After entering the preferred payment method, it will redirect you to the user details page, where you can check the order you just placed:

Butter Chicken	Main Course	350.00	4.30	60															
16	2024-04-04	16:37:08	360.00	<table><thead><tr><th>Food Item</th><th>Item Type</th><th>Item Price</th><th>Item Rating</th><th>Count</th></tr></thead><tbody><tr><td>Dal Makhani</td><td>Main Course</td><td>200.00</td><td>4.50</td><td>56</td></tr><tr><td>Gulab Jamun</td><td>Dessert</td><td>80.00</td><td>4.60</td><td>71</td></tr></tbody></table>	Food Item	Item Type	Item Price	Item Rating	Count	Dal Makhani	Main Course	200.00	4.50	56	Gulab Jamun	Dessert	80.00	4.60	71
Food Item	Item Type	Item Price	Item Rating	Count															
Dal Makhani	Main Course	200.00	4.50	56															
Gulab Jamun	Dessert	80.00	4.60	71															

Notice how the orders (Count) update for Gulab Jamun and Dal Makhani (increased each by one). In the assignment, it was mentioned about the snapshots for each query through a dialogue box. Or directly show before and after changes to be shown. In the pic above, Dal Makhani is 55, and after ordering, Dal Makhani now has a count of 56 in the user profile. Here is the code snippet of how an order gets added to the database and assigned to a random delivery agent.

```

@app.route('/ordersummary', methods=['GET', 'POST'])
def ordersummary():
    rest_id = request.args.get('rest_id')
    payment_method = request.args.get('payment_method')
    payment_status = request.args.get('payment_status')
    ordered_items = json.loads(request.args.get('ordered_items'))
    customer_id = session["customer_id"]
    order_status = "Processing"
    placed_time = datetime.now()
    amount = 0
    for item in ordered_items:
        item_ID = item["item_id"]
        item_quantity = item["item_quantity"]
        notes = item["notes"]
        item_price = item['item_price']
        if (item_quantity != "0"):
            amount += item_price * int(item_quantity)
    cursor = mysql.connection.cursor()
    cursor.execute('select max(order_id) from Orders;')
    order_ID = cursor.fetchone()
    order_ID = str(int(order_ID[0]) + 1)
    cursor.execute('select max(payment_id) from Payment;')
    payment_ID = cursor.fetchone()
    payment_ID = str(int(payment_ID[0]) + 1)
    cursor.execute('select max(agent_id) from delivery_agent;')
    num_delivery_agents = cursor.fetchone()
    agent_id = random.randint(1, int(num_delivery_agents[0]))
    cursor.execute('insert into payment (payment_id, payment_method, payment_status, amount, time) values (%s, %s, %s, %s, %s);')
    cursor.execute('insert into orders (order_id, customer_id, restaurant_id, payment_id, order_status, placed_time, amount) values (%s, %s, %s, %s, %s, %s, %s);')
    cursor.execute('insert into delivery (order_id, agent_id, customer_id, restaurant_id, delivery_review, delivery_rating, delivery_time) values (%s, %s, %s, %s, %s, %s, %s);')
    # ordered_items is list of dictionaries where each dictionary contains item_id, item_quantity, notes, item_price
    for item in ordered_items:
        item_ID = item["item_id"]
        item_quantity = item["item_quantity"]
        notes = item["notes"]
        item_price = item['item_price']
        if (item_quantity != "0"):
            cursor.execute('update food_item set order_count = order_count + 1 where item_id = %s;', (item_ID,))
            cursor.execute('insert into ordered_items (order_id, item_id, item_quantity, item_rating, item_review, notes) values (%s, %s, %s, %s, %s, %s);')
    mysql.connection.commit()

    # cursor.execute("select name from restaurant where restaurant_ID = %s;", (str(rest_id),))
    # rest_name = cursor.fetchone()[0]
    cursor.close()
    # flash("Order successfully submitted.")
    return render_template('customers/ordersummary.html', total_price=amount, items=ordered_items, rest_name="rest_name")

```

[INSERT AND UPDATE CLAUSE]

This code collects user input regarding payment method and desired food items for ordering and then proceeds to insert this information into the corresponding tables within the database. It also shows the total amount the customer is required to pay.

3. Restaurant Pages:

The restaurant pages include the details about the restaurant. Only people logged in as a restaurant can open the corresponding pages. After the user has logged in as a customer, the website will show a home page that includes the details about the restaurant, such as restaurant_name, rating, and contact details.

The orders from the given restaurant are shown below. The order details include order_id, the names of the items in the order, their quantities, any notes given, order_status, placed_time and the total_amount.

Taj Mahal Restaurant

Cuisine: Indian

Rating: 4.50

Submit

The user can edit the item_name, item_price, and item_type, including whether it is vegetarian or non-vegetarian and its availability. The user can not edit the rating of the item or the amount of orders placed.

Users can delete the item by clicking on the delete option provided.

In the backend:

```
@app.route('/restaurant')
def restaurant_details():
    cur = mysql.connection.cursor()
    restaurant_id = session["restaurant_ID"]
    # Fetch restaurant details
    cur.execute('''
    SELECT *
    FROM restaurant
    WHERE restaurant_id = %s
    ''', (restaurant_id,))
    restaurant_details_data = cur.fetchone()
    restaurant_details_columns = [col[0] for col in cur.description]
    restaurant_details = dict(zip(restaurant_details_columns, restaurant_details_data))

    # Fetch order details
    cur.execute('''
    SELECT
        o.order_id,
        GROUP_CONCAT(oi.item_quantity) AS item_quantities,
        GROUP_CONCAT(oi.notes) AS notes,
        GROUP_CONCAT(fi.item_name) AS item_names,
        SUM(fi.item_price) AS total_price,
        AVG(fi.item_rating) AS avg_food_rating,
        o.order_status,
        o.placed_time,
        o.amount
    FROM orders o
    JOIN ordered_items oi ON o.order_id = oi.order_id
    JOIN food_item fi ON oi.item_id = fi.item_id
```

We are using one query to collect the restaurant data from the database. Where as the second query is used to get the orders ordered by joining the food_item, orders and ordered_item tables.

```
def restaurant_details():
    order_details_columns = [col[0] for col in cur.description]
    order_details = [dict(zip(order_details_columns, row)) for row in order_details_data]

    cur.execute('''
    SELECT *
    FROM food_item
    JOIN restaurant ON food_item.restaurant_id = restaurant.restaurant_id
    WHERE restaurant.restaurant_id = %s
    ''', (restaurant_id,))
    food_item_data = cur.fetchall()
    food_item_columns = [col[0] for col in cur.description]
    food_items = [dict(zip(food_item_columns, row)) for row in food_item_data]

    return render_template("/restaurants/details.html", restaurant_details=restaurant_details, order_details=order_details)
```

[WHERE CLAUSE]

The restaurant's menu is fetched by joining the food_item and restaurant table.

For adding the item in the DB:

```

@app.route('/restaurant/add_item', methods=['GET', 'POST'])
def add_item():
    if request.method == 'POST':
        # Fetch form data
        item_name = request.form['item_name']
        item_price = float(request.form['item_price'])
        item_type = request.form['item_type']
        vegetarian = True if request.form.get('vegetarian') else False
        availability = True if request.form.get('availability') else False
        restaurant_id = session["restaurant_ID"]
        cursor = mysql.connection.cursor()
        cursor.execute('select max(item_id) from food_item;')
        item_ID = cursor.fetchone()
        item_ID = str(int(item_ID[0]) + 1)
        # order_count = 0
        # Insert food item details into the database
        cur = mysql.connection.cursor()
        cur.execute('''
            INSERT INTO food_item (item_id,item_name, item_price, item_type, vegetarian, availability, restaurant_id)
            VALUES (%s,%s, %s, %s, %s, %s, %s)
            ''', (item_ID, item_name, item_price, item_type, vegetarian, availability, restaurant_id))
        mysql.connection.commit()

        # Redirect the user back to the menu page after adding the new item
        return redirect(url_for('restaurant_details'))
    # return render_template('restaurants/details.html')
    else:
        return render_template('restaurants/add_item.html')

```

We are passing the details such as item_name, item_price, item_type, vegetarian and availability using the forms. Item_id is created by incrementing the highest item_id available. After the item is added, the user is redirected to the restaurant_details page.

For deleting the food_item from the DB:

```

@app.route('/delete_item/<item_id>')
def delete_item(item_id):
    cur = mysql.connection.cursor()
    cur.execute('''
        DELETE FROM food_item
        WHERE item_id = %s
        ''', (item_id,))
    mysql.connection.commit()
    return redirect(url_for('restaurant_details'))

```

[DELETE CLAUSE]

Food_item is deleted based on the item_id of the item.

Delivery Agent:

The third and final stakeholders are the delivery executives/agents. On logging into the application, the delivery executive would be able to see their own details.

```
@app.route('/delivery_dashboard', methods=['GET', 'POST'])
def index_deliveryagent():
    agent_id = session.get('agent_ID')
    cur = mysql.connection.cursor()
    cur.execute("SELECT * FROM Delivery WHERE agent_id = %s", (agent_id,))
    delivery_data = cur.fetchall()
    delivery_data_columns = [col[0] for col in cur.description]
    delivery = [dict(zip(delivery_data_columns, row)) for row in delivery_data]
    for delivery_item in delivery:
        # Fetch customer address
        customer_id = delivery_item['customer_id']
        cur.execute("SELECT a.building_name, a.street, a.pin_code, a.city, a.state FROM Customer_Address ca JOIN Delivery d ON ca.customer_id = d.customer_id WHERE d.id = %s", (customer_id,))
        customer_address_data = cur.fetchone()
        if customer_address_data:
            customer_address = {
                'building_name': customer_address_data[0],
                'street': customer_address_data[1],
                'pin_code': customer_address_data[2],
                'city': customer_address_data[3],
                'state': customer_address_data[4]
            }
        else:
            customer_address = None
        delivery_item['customer_address'] = customer_address

        # Fetch restaurant details
        restaurant_id = delivery_item['restaurant_id']
```

In the backend, we have fetched the details of the delivery agent. We stored the customer_id and restaurant_id in the delivery schema. For address, we join the respective tables to address table to get the addresses of customers and restaurants.
